§1. Introduction

1.1. Some basic definitions

Consider the equation $X^2 + 1 = 0$. Clearly, this equation has no roots over \mathbb{R} . Consider the set

$$\mathbb{C} = \{(a, b) : a, b \in \mathbb{R}\} = \mathbb{R}^2,$$

and define addition and subtraction over \mathbb{C} as

$$\begin{aligned}(a, b) + (c, d) &= (a + c, b + d) \\ (a, b) \cdot (c, d) &= (ac - bd, ad + bc).\end{aligned}$$

It is easy to show that $(\mathbb{C}, +, \cdot)$ is a field with additive identity $(0, 0)$ and multiplicative identity $(1, 0)$. Further observe that \mathbb{R} is a subfield of \mathbb{C} – consider the field homomorphism $\mathbb{R} \rightarrow \mathbb{C}$ defined by $a \mapsto (a, 0)$.

Now, we denote $\iota = (0, 1)$, and write (a, b) as $a + b\iota$.

Observe that the equation $X^2 + 1 = 0$ *does* have roots over \mathbb{C} since it can be written as $(X + \iota)(X - \iota)$. For the sake of completeness, we also note that the multiplicative identity of $a + b\iota$ is

$$\frac{1}{a + b\iota} = \frac{a - b\iota}{a^2 + b^2} = \frac{a}{a^2 + b^2} - \frac{b}{a^2 + b^2}\iota.$$

When writing $z = a + b\iota$ where $a, b \in \mathbb{R}$, we write $a = \Re z$ (the real part of z) and $b = \Im z$ (the imaginary part of z). We also define the absolute value $|z| = (a^2 + b^2)^{1/2}$ of z , and the *conjugate* $\bar{z} = a - b\iota$ of z . We clearly have

$$\begin{aligned}z\bar{z} &= |z|^2 \\ \Re z &= \frac{z + \bar{z}}{2} \\ \Im z &= \frac{z - \bar{z}}{2\iota}.\end{aligned}$$

It is easy to check that

$$\overline{z + w} = \bar{z} + \bar{w} \text{ and } \overline{z \cdot w} = \bar{z} \cdot \bar{w}.$$

We also have

$$\begin{aligned}\left| \frac{z}{w} \right| &= \frac{|z|}{|w|} \\ |\bar{z}| &= |z|.\end{aligned}$$

Exercise 1.1. Check that the set

$$M = \begin{pmatrix} \alpha & \beta \\ -\beta & \alpha \end{pmatrix} : \alpha, \beta \in \mathbb{R}$$

with matrix addition and multiplication is a field isomorphic to \mathbb{C} .

To close out the tedious part of things, we have

$$\begin{aligned}|z + w|^2 &= |z|^2 + |w|^2 + 2\Re(z\bar{w}) \\ |z + w| &\leq |z| + |w|\end{aligned}\tag{1.1}$$

Equation (1.1) is referred to as the *triangle inequality*.

1.2. Polar representations and roots

Consider $z = x + iy \in \mathbb{C}$. We may then define

$$x = r \cos \theta \quad y = r \sin \theta,$$

where $|z| = r$ and the angle θ is called the *argument* of z as is denoted $\theta = \arg z$. We typically restrict θ to $(-\pi, \pi]$. We denote $\text{cis } \theta = \cos \theta + i \sin \theta$. Therefore, we have

$$z = |z| \text{cis}(\arg z).$$

Observe that rather conveniently,

$$\text{cis } \theta_1 \cdot \text{cis } \theta_2 = \text{cis}(\theta_1 + \theta_2).$$

Therefore, inductively,

$$z_1 z_2 \cdots z_n = \left(\prod_i |z_i| \right) \cdots r_n \text{cis} \left(\sum_i \arg z_i \right).$$

In particular,

$$z^n = r^n \text{cis}(n\theta)$$

for any $n > 0$. If $z \neq 0$ (equivalently, $r \neq 0$), the above holds for all $n \in \mathbb{Z}$.

In the case where $r = 1$, we have

$$(\cos \theta + i \sin \theta)^n = \cos(n\theta) + i \sin(n\theta) \tag{1.2}$$

Equation (1.2) is referred to as *de Moivre's formula*.

Let us consider the equation $z^n = a$. This equation has n roots of the form

$$z = |a|^{1/n} \text{cis} \left(\frac{2k\pi + \arg z}{n} \right)$$

for $k = 0, 1, \dots, n-1$.

A *line* in the complex plane is a set of the form

$$L = \{z = a + tb : t \in \mathbb{R}\},$$

for some fixed $a, b \in \mathbb{C}$, where b is a *directional* vector whose absolute value may be assumed to be 1. Since $b \neq 0$, we equivalently have

$$L = \{z : \Im \left(\frac{z-a}{b} \right) = 0\}.$$

We can also define the half-planes

$$H_a = \{z : \Im \left(\frac{z-a}{b} \right) > 0\}$$

$$K_a = \{z : \Im \left(\frac{z-a}{b} \right) < 0\}.$$

Note that $H_a = a + H_0$, where the addition is Minkowski addition:

$$H_a = \{a + z : z \in H_0\}.$$

1.3. The extended plane

Define $\mathbb{C}_\infty = \mathbb{C} \cup \{\infty\}$ and let $S = \{(x_1, x_2, x_3) : x_1^2 + x_2^2 + x_3^2 = 1\}$ be the unit sphere in \mathbb{R}^3 . We shall show a bijection from \mathbb{C}_∞ to S .

Let $N = (0, 0, 1)$ be the ‘north pole’ of S , and orient \mathbb{C} (as \mathbb{R}^2) in the horizontal plane in a manner such that \mathbb{C} cuts S along the equator. For $z = x + iy \in \mathbb{C}$, let us define the corresponding point $Z = (x_1, x_2, x_3) \in S$. We shall draw a line connecting z to N , and let Z be the point of intersection (other than N) of this line with S . Finally, we shall map ∞ to N .

Let us define this more explicitly. The line through N and z is

$$L = \{tN + (1-t)z : t \in \mathbb{R}\}.$$

Then, letting $z = (x, y, 0)$, we have

$$t^2 + (1-t)^2|z|^2 = 1.$$

So,

$$|z|^2 = \frac{1-t^2}{(1-t)^2} = \frac{1+t}{1-t}$$

and

$$t = 1 - \frac{|z|^2 - 1}{|z|^2 + 1}.$$

Therefore, we map z to

$$Z = \left(\frac{2\Re z}{|z|^2 + 1}, \frac{2\Im z}{|z|^2 + 1}, \frac{|z|^2 - 1}{|z|^2 + 1} \right) \in S.$$

Based on this, we can define a distance metric between points in \mathbb{C}_∞ . For $z, z' \in \mathbb{C}_\infty$ mapping to $Z, Z' \in S$, we let $d(z, z')$ be the Euclidean distance between Z, Z' in \mathbb{R}^3 . More explicitly,

$$\begin{aligned} d(z, z')^2 &= (x_1 - x'_1)^2 + (x_2 - x'_2)^2 + (x_3 - x'_3)^2 \\ &= 2 - 2(x_1x'_1 + x_2x'_2 + x_3x'_3) \\ &= \frac{2|z - z'|}{((|z|^2 + 1)(|z'|^2 + 1))^{1/2}} \end{aligned}$$

when $z, z' \in \mathbb{C}$ and if $z' = \infty$ (so $Z' = (0, 0, 1)$), we have

$$d(z, z') =$$

This correspondence between points of S and \mathbb{C}_∞ is called the *stereographic projection*.

Exercise 1.2. If P is a plane in \mathbb{R}^3 and $\Lambda = P \cap S$ is a circle on S , show that the projection of Λ on \mathbb{C} under the stereographic projection is a circle as well (possibly a circle of infinite radius, namely a line).

1.4. Power series

In this section, we begin discussing convergence of series in \mathbb{C} and related properties.

Definition 1.1. If $a_n \in \mathbb{C}$ for every $n \geq 0$, the series $\sum_{n=0}^{\infty} a_n$ is said to *converge* to z iff for all $\epsilon > 0$, there exists $N \in \mathbb{N}$ such that

$$\left| \sum_{n=0}^m a_n - z \right| < \epsilon$$

for all $m \geq N$.

The series $\sum_{n=0}^{\infty} a_n$ is said to converge *absolutely* if $\sum_{n=0}^{\infty} |a_n|$ converges.

Theorem 1.1. \mathbb{C} is complete. That is, every Cauchy sequence in \mathbb{C} is convergent.

Proof. Suppose $\{x_n + iy_n\}$ is a Cauchy sequence in \mathbb{C} , where $x_n, y_n \in \mathbb{R}$ for each n . We then have the existence of $N \in \mathbb{N}$ such that for all $m, k > N$, $|(x_m - x_k) + i(y_m - y_k)| < \epsilon$. Consequently, $|x_m - x_k| < \epsilon$ and $|y_m - y_k| < \epsilon$. However, since \mathbb{R} is complete, this implies that (x_n) and (y_n) are convergent, completing the proof. ■

Theorem 1.2. If $\sum a_n$ converges absolutely, $\sum a_n$ converges.

Proof. Let $\epsilon > 0$, $z_n = \sum_{i=0}^n a_i$, and $S_n = \sum_{i=0}^n |a_i|$. Because \mathbb{C} is complete, it suffices to show that (z_n) is Cauchy. Since $\sum |a_n|$ is convergent, there exists $N \in \mathbb{N}$ such that $|S_m - S_k| < \epsilon$ for all $m, k > N$. Supposing $m > k$, we have

$$S_m - S_k = \sum_{i=k+1}^m |a_i|.$$

So,

$$\begin{aligned} |z_m - z_k| &= \left| \sum_{i=k+1}^m a_i \right| \\ &\leq \sum_{i=k+1}^m |a_i| < \epsilon, \end{aligned}$$

completing the proof. ■

Exercise 1.3. Show that $\sum_{n=0}^{\infty} z^n$ converges iff $|z| < 1$.

Theorem 1.3. For a given power series $\sum_{n=0}^{\infty} a_n(z-a)^n$, define the number of R ($0 \leq R \leq \infty$) by

$$\frac{1}{R} = \limsup_{n \rightarrow \infty} |a_n|^{1/n}.$$

Then,

- (a) If $|z - a| < R$, the series converges absolutely.
- (b) If $|z - a| > R$, the terms of the series become unbounded and the series diverges.
- (b) If $0 < r < R$, the series converges uniformly on the set $\{z : |z - a| \leq r\}$.

This R is referred to as the *radius of convergence* of the power series.

Proof.

- (a) We assume without loss of generality that $a = 0$. If $|z| < R$, there exists r with $|z| < r < R$. By the definition of R , for all $\epsilon > 0$, there exists $N \in \mathbb{N}$ such that

$$\frac{1}{R} - \epsilon < \sup_{k \geq n} |a_k|^{1/k} < \frac{1}{R} + \epsilon$$

for all $n > N$. If we take $\epsilon = 1/r - 1/R$, it follows that $|a_n|^{1/n} < 1/r$ for all $n > N$. That is, for all $n > N$, $|a_n| < 1/r^n$ and so

$$|a_n z^n| < \left(\frac{|z|}{r} \right)^n.$$

Therefore, $\sum_{n=N}^{\infty} a_n z^n$ is dominated by $\sum_{n=N}^{\infty} (|z|/r)^n$. Now however, we can just use the result of Exercise 1.3 to conclude absolute convergence since $|z|/r < 1$.

(b) Let $|z| > R$ and choose r with $|z| > r > R$. For $\epsilon > 0$, there exists $N \in \mathbb{N}$ such that

$$\frac{1}{R} - \epsilon < \sup_{k \geq n} |a_k|^{1/k} \text{ for all } n > N.$$

Choosing $\epsilon = 1/R - 1/r$,

$$|a_n|^{1/n} > 1/r$$

for infinitely many $n \in \mathbb{N}$. It follows that $|a_n z^n| > (|z|/r)^n$ for infinitely many $n \in \mathbb{N}$. Since $|z|/r > 1$, these terms become unbounded and therefore the series diverges.

(c) Now, suppose $r < R$ and choose ρ such that $r < \rho < R$. Similar to the argument in (a), we get that

$$|a_n| < \frac{1}{\rho^n} \text{ for all } n \geq N.$$

If $|z| \leq r$, $|a_n z^n| \leq (r/\rho)^n$ and $r/\rho < 1$. The Weierstrass M -test then gives that the power series converges uniformly on $\{z : |z| \leq r\}$. ■

It should be noted that we cannot conclude anything when $|z - a| = R$.

Theorem 1.4. If $\sum a_n(z - a)^n$ is a power series with radius of convergence R , then if it exists,

$$\lim_{n \rightarrow \infty} \left| \frac{a_n}{a_{n+1}} \right| = R.$$

Proof. Again, assume that $a = 0$ and let $\alpha = \lim |a_n/a_{n+1}|$, which we assume exists. Suppose that $|z| < \alpha$ and take $r \in \mathbb{R}$ such that $|z| < r < \alpha$. For all $\epsilon > 0$, there exists $N \in \mathbb{N}$ such that for $n \geq N$,

$$\alpha - \epsilon < \left| \frac{a_n}{a_{n+1}} \right| < \alpha + \epsilon.$$

Taking $\epsilon = \alpha - r$, $|a_n/a_{n+1}| > r$ for all $n \geq N$. Let $B = |a_N| r^N$. Then,

$$a_{N+1} r^{N+1} = |a_{N+1}| r \cdot r^N < |a_N| r^N = B.$$

Similarly, we get that $|a_n| r^n < B$ for all $n \geq N$. Therefore,

$$|a_n z^n| < B \left(\frac{|z|}{r} \right)^n$$

for all $n \geq N$. Thus, the sequence converges absolutely since $|z| < r$. Since $r < \alpha$ was arbitrary, this implies that $\alpha \leq R$.

On the other hand, if $|z| > \alpha$, take $r \in \mathbb{R}$ such that $|z| > r > \alpha$. Taking $\epsilon = r - \alpha$, we get $N \in \mathbb{N}$ such that

$$\left| \frac{a_n}{a_{n+1}} \right| < r$$

for all $n \geq N$. Letting $B = |a_N| r^N$ again, we once more obtain that $|a_n| r^n > B$ for all $n \geq N$. This gives that

$$|a_n z^n| > B \left(\frac{|z|}{r} \right)^n$$

for all $n \geq N$, and since $|z| > r$, the sequence diverges (we may assume that $B \neq 0$ by making N larger if required to ensure that $a_N \neq 0$ – if this is not possible, the problem is trivial since it means that (a_n) is eventually 0). Since the choice of r was arbitrary, this implies that $R \leq \alpha$, completing the proof. ■

Now, consider the series

$$\sum_{n=0}^{\infty} \frac{z^n}{n!}.$$

The radius of convergence of this series is ∞ . So, it converges for any complex number z , and convergence is uniform on every compact subset of \mathbb{C} .

The above defines a function $\exp : \mathbb{C} \rightarrow \mathbb{C}$.

We also denote $e^z = \exp(z)$.

Definition 1.2 (Differentiability). If G is an open set in \mathbb{C} and $f : G \rightarrow \mathbb{C}$, then f is said to be *differentiable* at a point $a \in G$ if the limit

$$\lim_{h \rightarrow 0} \frac{f(a+h) - f(a)}{h}$$

exists. If it exists, the value of this limit is denoted $f'(a)$ and is called the *derivative* of f at a .

If f is differentiable at each point of G , we say that f is differentiable on G . Note that if f is differentiable on G , then $f' : G \rightarrow \mathbb{C}$ is a function. If f' is continuous, f is said to be *continuously differentiable*.

Theorem 1.5. If $f : G \rightarrow \mathbb{C}$ is differentiable at a point $a \in G$, f is continuous at a .

Proof. The proof of this is direct:

$$\begin{aligned} \lim_{z \rightarrow a} |f(z) - f(a)| &= \left(\lim_{z \rightarrow a} \frac{|f(z) - f(a)|}{|z - a|} \right) \cdot \lim_{z \rightarrow a} |z - a| \\ &= f'(a) \cdot 0 = 0. \end{aligned}$$

■

Definition 1.3. A function $f : G \rightarrow \mathbb{C}$ is said to be *analytic* if f is continuously differentiable on G .

Let f, g be analytic on G and Ω respectively, and suppose that $f(G) \subseteq \Omega$. Then, $g \circ f$ is analytic on G and

$$(g \circ f)'(z) = g'(f(z)) \cdot f'(z)$$

for all $z \in G$. This is called the *chain rule*.

We shall show later that if f is differentiable then its derivative is continuous, and so f is analytic.

Theorem 1.6. Let $f(z) = \sum_{n=0}^{\infty} a_n(z-a)^n$ have radius of convergence $R > 0$. Then

(a) For each $k \geq 1$, the series

$$\sum_{n=k}^{\infty} n(n-1) \cdots (n-k+1) a_n (z-a)^{n-k}$$

has radius of convergence R .

(b) The function f is infinitely differentiable on $B(a, R)$ (the open ball of radius R centered at a), and further, $f^{(k)}(z)$ is given by the series in (a) for all $k \geq 1$ and $|z-a| < R$.

(c) For $n \geq 0$, $a_n = \frac{1}{n!} f^{(n)}(a)$.

Proof. Assume that $a = 0$.

- (a) Note that it suffices to prove the result for $k = 1$ (Why?). To show this, it is enough to show that

$$\limsup_{n \rightarrow \infty} |a_n|^{1/n} = \limsup_{n \rightarrow \infty} |na_n|^{1/(n-1)}$$

First, it is not difficult to show that $\lim_{n \rightarrow \infty} n^{1/(n-1)} = 1$. It may be shown that for any sequences $(c_n), (d_n)$ in \mathbb{R} where $c_n \geq 0$, if $\lim c_n = c$ and $\limsup d_n = d$, then $\limsup c_n d_n = cd$. Therefore, we are done if we show that $\limsup_{n \rightarrow \infty} |a_n|^{1/n} = \limsup_{n \rightarrow \infty} |a_n|^{1/(n-1)}$.

$$\sum_{n=0}^{\infty} a_n z^n = a_0 + z \sum_{n=0}^{\infty} a_{n+1} z^n.$$

Let R' be the radius of convergence of $\sum_{n=0}^{\infty} a_{n+1} z^n$. We want to show that $R' = R$.

If $|z| < R'$, then

$$\sum |a_n z^n| \leq |a_0| + |z| \sum_{n=0}^{\infty} |a_{n+1} z^n| < \infty,$$

so $R' \leq R$. On the other hand, if $|z| < R$ and $z \neq 0$,

$$\sum |a_{n+1} z^n| < \frac{1}{|z|} \left(\sum |a_n z^n| + |a_0| \right) < \infty,$$

so $R \leq R'$ and we are done.

- (b) Once again, it suffices to prove the result for $k = 0$. For $|z| < R$ and $g(z) = \sum_{n=1}^{\infty} na_n z^{n-1}$,

$$s_n(z) = \sum_{k=0}^n a_k z^k \text{ and } R_n(z) = \sum_{k=n+1}^{\infty} a_k z^k,$$

fix a point $w \in B(0, R)$ and r such that $|w| < r < R$. We wish to show that $f'(w)$ exists and is equal to $g(w)$. Let $\delta > 0$ be arbitrary with $\overline{B(w, \delta)} \subseteq B(0, r)$. Letting $z \in B(w, \delta)$, we have

$$\begin{aligned} \frac{f(z) - f(w)}{z - w} - g(w) &= \frac{s_n(z) - s_n(w)}{z - w} - s'_n(w) + s'_n(w) - g(w) + \frac{R_n(z) - R_n(w)}{z - w} \\ &= \frac{s_n(z) - s_n(w)}{z - w} - s'_n(w) + s'_n(w) - g(w) + \frac{1}{z - w} \sum_{k=n+1}^{\infty} a_k (z^k - w^k) \\ &= \frac{s_n(z) - s_n(w)}{z - w} - s'_n(w) + s'_n(w) - g(w) + \sum_{k=n+1}^{\infty} a_k \frac{z^k - w^k}{z - w}. \end{aligned}$$

We have

$$|z^k - w^k| = |z - w| |z^{k-1} + z^{k-2}w + \cdots + w^{k-1}| \leq |z - w| k r^{k-1}.$$

Therefore,

$$\left| \frac{R_n(z) - R_n(w)}{z - w} \right| \leq \sum_{k=n+1}^{\infty} |a_k| k r^{k-1}.$$

Since $r < R$, $\sum_{k=1}^{\infty} |a_k| k r^{k-1}$ converges and so for any $\epsilon > 0$, there exists $N_1 \in \mathbb{N}$ such that

$$\left| \frac{R_n(z) - R_n(w)}{z - w} \right| < \epsilon/3.$$

Since $\lim s'_n(w) = g(w)$, there exists $N_2 \in \mathbb{N}$ such that

$$|s'_n(w) - g(w)| < \epsilon/3$$

for $n \geq N_2$. Choose $n \geq \max(N_1, N_2)$. Then, there exists $\delta > 0$ such that whenever $0 < |z - w| < \delta$,

$$\left| \frac{s_n(z) - s_n(w)}{z - w} - s'_n(w) \right| < \epsilon/3.$$

Putting all these together, we get the desideratum.

(c) This is straightforward using the explicit expression for $f^{(k)}(a)$. ■

If the series $f(z) = \sum_{n=0}^{\infty} a_n(z-a)^n$ has radius of convergence $R > 0$, then f is analytic on $B(a, R)$. Therefore, f is analytic on \mathbb{C} .

1.5. Cauchy-Riemann Equations

Let $f : G \rightarrow \mathbb{C}$ be analytic and let

$$u(x, y) = \Re(f(x + iy)), v(x, y) = \Im(f(x + iy))$$

for $x + iy \in G$. Let us evaluate the limit

$$f'(z) = \lim_{h \rightarrow 0} \frac{f(z+h) - f(z)}{h}.$$

in two different ways.

First, if we let $h \rightarrow 0$ through real values, we get

$$f'(z) = \frac{\partial u}{\partial x}(x, y) + i \frac{\partial v}{\partial x}(x, y).$$

Along the imaginary axis, we get

$$f'(z) = -i \frac{\partial u}{\partial y}(x, y) + \frac{\partial v}{\partial y}(x, y).$$

Therefore,

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y} \text{ and } \frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x}.$$

Supposing that u and v have continuous second derivative (we shall later show that they are infinitely differentiable), we have that

$$\frac{\partial^2 u}{\partial x^2} = \frac{\partial^2 v}{\partial x \partial y} \text{ and } \frac{\partial^2 u}{\partial y^2} = \frac{\partial^2 v}{\partial y \partial x}.$$

Therefore, since the second derivatives are continuous,

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0. \tag{1.3}$$

A function u with continuous second partial derivatives satisfying Equation (1.3) is said to be *harmonic*. Similarly, v is also harmonic.

Theorem 1.7. Let u, v be real-valued functions defined on an open connected set (a *region*) G and suppose that they have continuous second partial derivatives. Then, $f : G \rightarrow \mathbb{C}$ defined by $f(z) = u(z) + iv(z)$ is analytic iff u and v satisfy the Cauchy-Riemann equations.

Proof. We have already shown the forward direction.

For the other direction, let $z = x + iy \in G$ and $B(z, r) \subseteq G$. Let $h = s + it \in B(0, r)$. Our goal is to show that for all $\epsilon > 0$, there exists $\delta > 0$ such that

$$\left| \frac{f(z+h) - f(z) - f'(z)h}{h} \right| < \epsilon$$

for all $h \in B(0, \delta)$ for some $f'(z) \in \mathbb{C}$. Note that

$$u(x + s, y + t) - u(x, y) = (u(x + s, y + t) - u(x, y + t)) + (u(x, y + t) - u(x, y)).$$

Now, for fixed $t \in (-r, r)$, $s \mapsto u(x + s, y + t)$ is a differentiable function on $(-r, r)$. We apply the mean value theory to conclude that there exist $s_1, t_1 \in (-r, r)$ for each $s + it \in B(0, r)$ such that $|s_1| < |s|$, $|t_1| < |t|$, and

$$\begin{aligned} u(x + s, y + t) - u(x, y + t) &= u_x(x + s_1, y + t)s \\ u(x, y + t) - u(x, y) &= u_y(x, y + t_1)t. \end{aligned}$$

Now, let

$$\varphi(s, t) = (u(x + s, y + t) - u(x, y)) - (u_x(x, y)s + u_y(x, y)t).$$

We get that

$$\varphi(s, t) = (su_x(x + s_1, y + t) - su_x(x, y)) + (tu_y(x, y + t_1) - tu_y(x, y)).$$

So,

$$\frac{\varphi(s, t)}{s + it} = \frac{s}{s + it} (u_x(x + s_1, y + t) - u_x(x, y)) + \frac{t}{s + it} (u_y(x, y + t_1) - u_y(x, y))$$

and on taking the limit of both sides as $s + it \rightarrow 0$, we can use the fact that $|s| \leq |s + it|$, $|t| \leq |s + it|$, $|s_1| < |s|$, $|t_1| < |t|$, and the continuity of u_x, u_y , to conclude that

$$\lim_{s+it \rightarrow 0} \frac{\varphi(s, t)}{s + it} = 0.$$

Therefore,

$$u(x + s, y + t) - u(x, y) = u_x(x, y)s + u_y(x, y)t + \varphi(s, t).$$

We get a similar equation for v as well, with a function ψ (in place of φ). Combining the two,

$$\begin{aligned} \frac{f(z + s + it) - f(z)}{s + it} &= \frac{u(x + s, y + t) - u(x, y)}{s + it} + \iota \frac{v(x + s, y + t) - v(x, y)}{s + it} \\ &= \frac{su_x(x, y) + tu_y(x, y) + \varphi(s, t) + \iota (sv_x(x, y) + tv_y(x, y) + \psi(s, t))}{s + it} \\ &= \frac{u_x(x, y)(s + it) + \iota v_x(x, y)(s + it) + \varphi(s, t) + \iota \psi(s, t)}{s + it}, \end{aligned}$$

where we used Cauchy-Riemann equations in the final step and thus,

$$\lim_{s+it \rightarrow 0} \frac{f(z + s + it) - f(z)}{s + it} = u_x(x, y) + \iota v_x(x, y),$$

completing the proof. Since u_x and v_x are continuous, f' is continuous and f is analytic. ■

A next question is: given some u such that

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0,$$

when does there exist harmonic v such that $u + \iota v$ is analytic? Such a v is referred to as a *harmonic conjugate* of u . It turns out that the answer is not always. Indeed, $u(x, y) = \log((x^2 + y^2)^{1/2})$ on $\mathbb{C} \setminus \{0\}$, despite being harmonic, does not have a harmonic conjugate.

Theorem 1.8. Let G be either the entirety of \mathbb{C} or some open disk. If $u : G \rightarrow \mathbb{R}$ is a harmonic function, then u has a harmonic conjugate.

Proof. Let $G = B(0, R)$ for some $0 < R \leq \infty$ and let $u : G \rightarrow \mathbb{R}$ be analytic. Define

$$v(x, y) = \int_0^y u_x(x, t) dt + \varphi(x)$$

so that $u_x = v_y$. We shall determine φ such that $v_x = -u_y$. Differentiating with respect to x , we get

$$\begin{aligned} v_x(x, y) &= \int_0^y u_{xx}(x, t) dt + \varphi'(x) \\ &= - \int_0^y u_{yy}(x, t) dt + \varphi'(x) \\ &= -u_y(x, y) + u_y(x, 0) + \varphi'(x). \end{aligned}$$

Therefore, $\varphi'(x) = -u_y(x, 0)$, and the function

$$v(x, y) = \int_0^y u_x(x, t) dt - \int_0^x u_y(s, 0) ds$$

is a harmonic conjugate of u . ■

The above proof requires that the entire segments $[(0, 0), (x, 0)]$ $[(x, 0), (x, y)]$ are contained in G , which is true when we are on a disk.

1.6. Transformations

Consider the two hyperbolas defined by

$$\begin{aligned} x^2 - y^2 &= c \\ 2xy &= d, \end{aligned}$$

where $c, d \neq 0$.

This gives

$$y = \pm \sqrt{\frac{-c \pm \sqrt{d^2 + c^2}}{2}}.$$

Consider the functions

$$\begin{aligned} u(x, y) &= x^2 - y^2 \\ v(x, y) &= 2xy. \end{aligned}$$

The two hyperbolas above are mapped by this $f = u + iv$ to the straight lines $u = c$ and $v = d$.

Definition 1.4. A *path* in a region $G \subseteq \mathbb{C}$ is a continuous function $\gamma : [a, b] \rightarrow G$ for some interval $[a, b]$ in \mathbb{R} . If $\gamma'(t)$ exists for each $t \in [a, b]$ and $\gamma' : [a, b] \rightarrow \mathbb{C}$ is continuous, then γ is

By the existence of γ' , we mean that the two-sided limit

$$\lim_{h \rightarrow 0} \frac{\gamma(t+h) - \gamma(t)}{h}$$

exists for $t \in (a, b)$ and the right and left sided limits exist for $t = a, b$ respectively. This is equivalent to saying that $\Re \gamma$ and $\Im \gamma$ have derivatives.

Suppose $\gamma : [a, b] \rightarrow G$ is a smooth path and for some $t_0 \in (a, b)$, $\gamma'(t_0) \neq 0$. Then, γ has a *tangent line* at the point $z_0 = \gamma(t_0)$. This line goes through the point z_0 in the direction of the vector $\gamma'(t_0)$, that is, the slope of the line is

$$\tan(\arg \gamma'(t_0)).$$

If γ_1 and γ_2 are two smooth paths with $\gamma_1(t_1) = \gamma_2(t_2) = z_0$ and $\gamma'_1(t_1), \gamma'_2(t_2) \neq 0$, then define the *angle* between the paths γ_1, γ_2 at z_0 to be $\arg(\gamma'_2(t_2)) - \arg(\gamma'_1(t_1))$.

Suppose γ is a smooth path in G and $f : G \rightarrow \mathbb{C}$ is analytic. Then, $\sigma = f \circ \gamma$ is also a smooth path and $\sigma'(t) = f'(\gamma(t)) \cdot \gamma'(t)$. Further, if t_0 is a fixed point of f with $\gamma(t_0) = z_0$,

$$\arg(\sigma'(t_0)) - \arg(\gamma'(t_0)) = \arg(f'(z_0)).$$

Letting γ_1, γ_2 be smooth paths with $\gamma_1(t_1) = \gamma_2(t_2) = z_0$ with non-zero derivatives at t_1, t_2 respectively, and let $\sigma_1 = f \circ \gamma_1, \sigma_2 = f \circ \gamma_2$. Further suppose that the two paths γ_1, γ_2 are not tangent to each other at z_0 . Then,

$$\arg(\gamma'_2(t_2)) - \arg(\gamma'_1(t_1)) = \arg(\sigma'_2(t_2)) - \arg(\sigma'_1(t_1)).$$

This says that the angle between two paths are preserved after applying an analytic function to both. A function f satisfying this is said to have the *angle-preserving property*.

Definition 1.5. A function $f : G \rightarrow \mathbb{C}$ which has the angle-preserving property and also has

$$\lim_{z \rightarrow a} \left| \frac{f(z) - f(a)}{z - a} \right|$$

existing is called a *conformal map*.

It turns out that a function f is a conformal map if and only if it is analytic and $f'(z) \neq 0$ for all z (How?).

Definition 1.6. A mapping of the form

$$S(z) = \frac{az + b}{cz + d}$$

is called a *linear fractional transformation*. If we further have that $ad - bc \neq 0$, then $S(z)$ is called a *Möbius transformation*.

We have

$$S'(z) = \frac{ad - bc}{(cz + d)^2}.$$

If $w = S(z)$, it is relatively simple to show that

$$z = S^{-1}(w) = \frac{dw - b}{-cw + a}.$$

Therefore, the inverse of a Möbius transformation is a Möbius transformation. The composition of two Möbius transformations is a Möbius transformation as well.

Also observe that the coefficients a, b, c, d for a given Möbius transformation are not unique since we can multiply them by a constant. We may also extend S to \mathbb{C}_∞ with $S(\infty) = a/c$ and $S(-d/c) = \infty$.

$S(z) = z + a$ is called a *translation*, $S(z) = az$ with $a \neq 0$ is called a *dilation*, $S(z) = e^{i\theta}z$ is called a *rotation*, and $S(z) = 1/z$ is called the *inversion*. We shall see later that any Möbius transformation is a composition of these five types of transformations.

What are the fixed points of a Möbius transformation S ? $S(z) = z$ gives

$$cz^2 + (a - d)z + b = 0.$$

Therefore, a Möbius transformation has at most two fixed points unless $S(z) = z$ for all $z \in \mathbb{C}_\infty$.

Let $a, b, c \in \mathbb{C}_\infty$ be distinct with $S(a) = \alpha$, $S(b) = \beta$, $S(c) = \gamma$. Let T be another Möbius transformation with $T(a) = \alpha$, $T(b) = \beta$, $T(c) = \gamma$. Then $T^{-1} \circ S$ has three (distinct) fixed points, and therefore $S = T$.

Therefore, any Möbius transformation is uniquely determined by its value at any three distinct points.

Let $z_2, z_3, z_4 \in \mathbb{C}_\infty$ be distinct. Define $S : \mathbb{C}_\infty \rightarrow \mathbb{C}_\infty$ by

$$S(z) = \begin{cases} \frac{(z-z_3)/(z-z_4)}{(z_2-z_3)/(z_2-z_4)}, & z_2, z_3, z_4 \in \mathbb{C}, \\ \frac{z_2-z_4}{z-z_4}, & z_3 = \infty, \\ \frac{z-z_3}{z_2-z_3}, & z_4 = \infty. \end{cases}$$

In any case, $S(z_2) = 1$, $S(z_3) = 0$, $S(z_4) = \infty$, and S is the only transformation having this property.

Definition 1.7. If $z_1 \in \mathbb{C}_\infty$, then (z_1, z_2, z_3, z_4) is referred to as the *cross-ratio* of z_1, z_2, z_3, z_4 and is the image of z_1 under the Möbius transformation described above, which is the unique Möbius transformation taking z_2 to 1, z_3 to 0, and z_4 to ∞ .

For example, $(z_2, z_2, z_3, z_4) = 1$ and $(z, 1, 0, \infty) = z$.

If M is any Möbius transformation with $M(w_2) = 1$, $M(w_3) = 0$, $M(w_4) = \infty$, then $M(z) = (z, w_2, w_3, w_4)$ for any $z \in \mathbb{C}_\infty$.

Theorem 1.9. If z_2, z_3, z_4 are distinct points and T is any Möbius transformation, then

$$(z_1, z_2, z_3, z_4) = (Tz_1, Tz_2, Tz_3, Tz_4).$$

Proof. Let $S(z) = (z, z_2, z_3, z_4)$. If $M = ST^{-1}$, then

$$M(T(z_2)) = 1, \quad M(T(z_3)) = 0, \quad M(T(z_4)) = \infty.$$

Therefore, $M = (z, Tz_2, Tz_3, Tz_4)$. That is,

$$ST^{-1}z = (z, Tz_2, Tz_3, Tz_4)$$

for all $z \in \mathbb{C}_\infty$. Setting $z = Tz_1$ yields the required. ■

Lemma 1.10. If $\{z_2, z_3, z_4\}, \{w_2, w_3, w_4\} \subseteq \mathbb{C}_\infty$, then there exists a unique Möbius transformation S with $Sz_i = w_i$ for each i .

We omit the proof of the above.

Lemma 1.11. Let $\{z_1, z_2, z_3, z_4\} \subseteq \mathbb{C}_\infty$. Then, (z_1, z_2, z_3, z_4) is real iff the four points lie on a circle.

Proof. Define $S : \mathbb{C}_\infty \rightarrow \mathbb{C}_\infty$ by $Sz = (z, z_2, z_3, z_4)$. We are done if we show that $S^{-1}(\mathbb{R}_\infty)$ is a circle (since a circle is uniquely determined by three distinct points on it).

Let $S^{-1}(z) = (az + b)/(cz + d)$.

First, let us show that $S^{-1}(\mathbb{R}_\infty) \subseteq \Gamma$ for a circle Γ in \mathbb{C}_∞ . Let $w \in S^{-1}(\mathbb{R}_\infty)$. Then, $Sw = \overline{Sw}$ so

$$\frac{aw + b}{cw + d} = \frac{\overline{aw + b}}{\overline{cw + d}}.$$

This gives that

$$(a\bar{c} - \bar{a}c)|w|^2 + (a\bar{d} - \bar{a}d)w + (b\bar{c} - \bar{b}c)\bar{w} + (b\bar{d} - \bar{b}d) = 0. \quad (**)$$

If $a\bar{c}$ is real, we get that

$$\Im \left((a\bar{d} - \bar{a}d)w + b\bar{d} \right) = 0,$$

which is a circle through ∞ (a line).

If on the other hand $a\bar{c}$ is not real, then Equation $(*)$ becomes

$$2\iota \underbrace{\Im(a\bar{c})}_{\alpha \neq 0} |w|^2 + (a\bar{d} - b\bar{c})w + (b\bar{c} - a\bar{d})\bar{w} + (b\bar{d} - \bar{b}d) = 0.$$

Dividing by $2\iota\alpha$,

$$|w|^2 + \frac{(a\bar{d} - b\bar{c})w}{2\iota\alpha} + \frac{(b\bar{c} - a\bar{d})\bar{w}}{2\iota\alpha} + \frac{(b\bar{d} - \bar{b}d)}{2\iota\alpha} = 0.$$

Since α is real,

$$\frac{(b\bar{c} - a\bar{d})\bar{w}}{2\iota\alpha} = \frac{(a\bar{d} - b\bar{c})w}{2\iota\alpha}$$

and

$$\frac{(b\bar{d} - \bar{b}d)}{2\iota\alpha}$$

is real. This gives

$$|w|^2 + \bar{\gamma}w + \gamma\bar{w} - \delta = 0$$

for some $\gamma \in \mathbb{C}, \delta \in \mathbb{R}$. This is equivalent to $|w + \gamma| = (|\gamma|^2 + \delta)^{1/2}$, which is the equation of a circle¹.

Letting $T = S^{-1}$ and Γ be the circle obtained in the previous part of the proof, we must now show that $T(\mathbb{R}_\infty) = \Gamma$. Since \mathbb{R}_∞ is connected and compact and T is a homeomorphism, $T(\mathbb{R}_\infty)$ is a closed arc, say Γ_1 , of Γ . If $\Gamma_1 \neq \Gamma$, let z_1, z_2 be the endpoints of this arc. If $T(\infty) = z_3$ which is distinct from z_1, z_2 , then $\mathbb{R}_\infty \setminus \{\infty\}$ is connected but $\Gamma_1 \setminus \{z_1\}$ is disconnected, which is a contradiction. So, suppose $T(\infty) = z_1$. Then, $\mathbb{R}_\infty \setminus \{\infty, T^{-1}(z_2)\}$ is disconnected but $\Gamma_1 \setminus \{z_1, z_2\}$ is connected, yielding a contradiction once more and completing the proof. ■

Next, we give a more general version of the above.

Theorem 1.12. A Möbius transformation takes circles to circles.

Note that Lemma 1.11 follows from this since \mathbb{R}_∞ is a circle (of infinite radius) in \mathbb{C}_∞ .

Proof. Let Γ be a circle in \mathbb{C}_∞ and S a Möbius transformation. Let z_2, z_3, z_4 be three distinct points on Γ , and set $w_j = Sz_j$ for each j . We claim that $S(\Gamma)$ is the circle Γ' determined by w_2, w_3, w_4 . Indeed,

$$(z, z_2, z_3, z_4) = (Sz, w_2, w_3, w_4)$$

for any z , and if $z \in \Gamma$, the LHS is real by Lemma 1.11, and using the same theorem on the RHS completes the proof. ■

Definition 1.8. Let Γ be a circle through z_2, z_3, z_4 . The points $z, z^* \in \mathbb{C}_\infty$ are said to be *symmetric* with respect to Γ if

$$(z^*, z_2, z_3, z_4) = \overline{(z, z_2, z_3, z_4)}.$$

Remark. The above definition only depends on Γ , not the choice of z_2, z_3, z_4 .

¹it may be checked that $|\gamma|^2 + \delta$ is a positive real by substituting their values

Observe that z is symmetric with respect to itself with respect to Γ if and only if $z \in \Gamma$. Indeed, it implies that (z, z_2, z_3, z_4) is real, which by Lemma 1.11 implies that $z \in \Gamma$.

What does it mean for z, z^* to be symmetric?

If Γ is a straight line, z, z^* are symmetric with respect to Γ iff their perpendicular bisector is equal to Γ . That is, the line joining z, z^* is perpendicular to Γ and they are the same distance from Γ (but on opposite sides). Indeed, choosing $z_4 = \infty$, we get that

$$\frac{z^* - z_3}{z_2 - z_3} = \frac{\bar{z} - \bar{z}_3}{\bar{z}_2 - \bar{z}_3},$$

so

$$|z - z_3| = |z^* - z_3|$$

for all $z_3 \in \Gamma$.

Now, suppose that $\Gamma = \{z : |z - a| = R\}$ for some $0 < R < \infty$. We extensively use Theorem 1.9 and the five types of Möbius transformations in the following sequence of equations. Then,

$$\begin{aligned} (z^*, z_2, z_3, z_4) &= \overline{(z, z_2, z_3, z_4)} \\ &= \overline{(z - a, z_2 - a, z_3 - a, z_4 - a)} \\ &= \left(\bar{z} - \bar{a}, \frac{R^2}{z_2 - a}, \frac{R^2}{z_3 - a}, \frac{R^2}{z_4 - a} \right) \\ &= \left(\frac{R^2}{\bar{z} - \bar{a}}, z_2 - a, z_3 - a, z_4 - a \right) \\ &= \left(\frac{R^2}{\bar{z} - \bar{a}} + a, z_2, z_3, z_4 \right). \end{aligned}$$

Therefore, $z^* = a + \frac{R^2}{\bar{z} - \bar{a}}$, that is,

$$(z^* - a)(\bar{z} - \bar{a}) = R^2.$$

Since

$$\frac{z^* - a}{z - a} = \frac{R^2}{|z - a|^2} > 0$$

is real, it follows that z^* is on the ray $\{a + t(z - a) : 0 < t < \infty\}$. We also have that

$$|z^* - a||z - a| = R^2,$$

so one can easily obtain z^* from z or vice-versa.

Lemma 1.13 (Symmetry Principle). If a Möbius transformation takes a circle Γ_1 to the circle Γ_2 , then any pair of points symmetric with respect to Γ_1 is mapped to a pair of points symmetric with respect to Γ_2 .

Proof. The proof of this is near-direct.

$$\begin{aligned} (Tz, Tz_2, Tz_3, Tz_4) &= (z^*, z_2, z_3, z_4) \\ &= \overline{(z, z_2, z_3, z_4)} \\ &= \overline{(Tz, Tz_2, Tz_3, Tz_4)}. \end{aligned}$$

■

Definition 1.9. If Γ is a circle, then an *orientation* for Γ is an ordered triple (z_1, z_2, z_3) of points in Γ .

An orientation is used to represent a “direction” of the circle, where we “go” from z_1 to z_2 to z_3 .

Let $\Gamma = \mathbb{R}$ and $z_1, z_2, z_3 \in \mathbb{R}$. Also put $Tz = (z, z_1, z_2, z_3)$. Since $T(\mathbb{R}_\infty) = \mathbb{R}_\infty$, a, b, c, d can be chosen to be reals. Then,

$$\begin{aligned} Tz &= \frac{az + b}{cz + d} \\ &= \frac{az + b}{|cz + d|^2} (c\bar{z} + d) \\ &= \frac{1}{|cz + d|^2} (ac|z|^2 + bd + bc\bar{z} + adz). \end{aligned}$$

So,

$$\Im(z, z_1, z_2, z_3) = \frac{ad - bc}{|cz + d|^2} \Im z$$

and thus, $\{z : \Im(z, z_1, z_2, z_3)\}$ is either the upper or lower half-plane depending on whether $ad - bc$ is positive or negative. Note that $ad - bc$ is the determinant of $\begin{pmatrix} a & b \\ c & d \end{pmatrix}$.

Let Γ be an arbitrary circle and suppose that $z_1, z_2, z_3 \in \Gamma$. Then, for any Möbius transformation S ,

$$\begin{aligned} \{z : \Im(z, z_1, z_2, z_3) > 0\} &= \{z : \Im(Sz, Sz_1, Sz_2, Sz_3) > 0\} \\ &= S^{-1}\{z : \Im(z, Sz_1, Sz_2, Sz_3) > 0\}. \end{aligned}$$

So, if S is chosen to map Γ to \mathbb{R}_∞ , then the above set is equal to S^{-1} of either the upper or lower halfspace.

Definition 1.10. If z_1, z_2, z_3 is an orientation of Γ , we denote the *right side* and *left side* of Γ (with respect to (z_1, z_2, z_3)) to be

$$\{z : \Im(z, z_1, z_2, z_3) > 0\} \text{ and } \{z : \Im(z, z_1, z_2, z_3) < 0\}$$

respectively.

Theorem 1.14 (Orientation Principle). Let Γ_1, Γ_2 be circles in \mathbb{C}_∞ such that $T\Gamma_1 = \Gamma_2$ for some Möbius transformation T . Let (z_1, z_2, z_3) be an orientation of Γ_1 . Then, T takes the right side (resp. left side) of Γ_1 with respect to the orientation (z_1, z_2, z_3) to the right side (resp. left side) of Γ_2 with respect to the orientation (Tz_1, Tz_2, Tz_3) .

The proof of the above is left as an exercise to the reader.

Since $(z, 1, 0, \infty) = z$ by definition, the right side of \mathbb{R}_∞ with respect to the orientation $(1, 0, \infty)$ is the upper half-plane.

Exercise 1.4. Find an analytic function $f : G \rightarrow \mathbb{C}$ where $G = \{z : \Re z > 0\}$, such that $f(G) = \{z : |z| < 1\}$.

Similar to the above exercise, one may show that

$$g(z) = \frac{e^z - 1}{e^z + 1}$$

maps the infinite strip $\{z : |\Im z| < \pi/2\}$ to the open unit disk D .

§2. Integration

2.1. Basic definitions

2.1.1. Integrals of real functions

First, let us recall the definition of the Riemann² integral of functions on \mathbb{R} .

Definition 2.1 (Riemann Integral). Let $[a, b]$ be a given interval. A *partition* \mathcal{P} of $[a, b]$ is a finite set of points x_0, x_1, \dots, x_n where

$$a = x_0 \leq x_1 \leq \dots \leq x_{n-1} \leq x_n = b.$$

We also write $\Delta x_i = x_i - x_{i-1}$ for $i = 1, 2, \dots, n$.

For a bounded real function f on $[a, b]$ and each partition \mathcal{P} of $[a, b]$, we set

$$M_i = \sup_{x_{i-1} \leq x \leq x_i} f(x), \quad m_i = \inf_{x_{i-1} \leq x \leq x_i} f(x).$$

Further, set

$$U(\mathcal{P}, f) = \sum_{i=1}^n M_i \Delta x_i, \quad L(\mathcal{P}, f) = \sum_{i=1}^n m_i \Delta x_i$$

as the upper and lower Riemann sum respectively, and finally,

$$\overline{\int_a^b} f \, dx = \inf_{\mathcal{P}} U(\mathcal{P}, f), \quad \underline{\int_a^b} f \, dx = \sup_{\mathcal{P}} L(\mathcal{P}, f)$$

as the upper and lower Riemann integrals of f .

cc

Next, we define the slightly more general Riemann-Stieltjes integral. Note that this is the same as the usual Riemann integral when α is the identity function.

Definition 2.2 (Riemann-Stieltjes Integral). Let $\alpha : [a, b] \rightarrow \mathbb{R}$ be a monotonically increasing function on $[a, b]$. Corresponding to each partition \mathcal{P} of $[a, b]$, write $\Delta \alpha_i = \alpha(x_i) - \alpha(x_{i-1})$. Clearly, $\Delta \alpha_i \geq 0$ for each i . For any real function f which is bounded on $[a, b]$, we put

$$U(\mathcal{P}, f, \alpha) = \sum_{i=1}^n M_i \Delta \alpha_i, \quad L(\mathcal{P}, f, \alpha) = \sum_{i=1}^n m_i \Delta \alpha_i,$$

where M_i, m_i are defined as in the definition of the Riemann integral. We then define

$$\overline{\int_a^b} f \, d\alpha = \inf_{\mathcal{P}} U(\mathcal{P}, f, \alpha), \quad \underline{\int_a^b} f \, d\alpha = \sup_{\mathcal{P}} L(\mathcal{P}, f, \alpha).$$

If these two are equal, we say that f is *Riemann-Stieltjes integrable* with respect to α on $[a, b]$ and denote the common value as $\int_a^b f \, d\alpha$.

²technically the Darboux integral?

We also remark that

$$\int_a^b f \, d\alpha = \lim_{\max \Delta\alpha_k \rightarrow 0} \sum_{k=1}^n f(\tau_k) \Delta\alpha_k,$$

where $x_{k-1} \leq \tau_k \leq x_k$ for each k .

More generally, we define the *mesh* of \mathcal{P} with respect to α as

$$\|\mathcal{P}\| = \max\{\Delta\alpha_i : 1 \leq i \leq n\}.$$

So for all $\epsilon > 0$, there exists $\delta > 0$ such that for any partition \mathcal{P} of $[a, b]$ with $\|\mathcal{P}\| < \delta$, then

$$\left| \sum_{k=1}^n f(\tau_k) \Delta\alpha_k - \int_a^b f \, d\alpha \right| < \epsilon$$

for any choice of points $x_{k-1} \leq \tau_k \leq x_k$.

2.2. Riemann-Stieltjes integrals of complex-valued functions

Definition 2.3. A function $\gamma : [a, b] \rightarrow \mathbb{C}$ for $[a, b] \subseteq \mathbb{R}$ is said to be of *bounded variation* if there exists $M > 0$ such that for any partition $\mathcal{P} = \{a = t_0 < t_1 < \cdots < t_{m-1} < t_m = b\}$ of $[a, b]$,

$$v(\gamma; \mathcal{P}) = \sum_{k=1}^m |\gamma(t_k) - \gamma(t_{k-1})| \leq M.$$

The *total variation* $V(\gamma)$ of γ is defined by

$$V(\gamma) = \sup\{v(\gamma; \mathcal{P}) : \mathcal{P} \text{ is a partition of } [a, b]\}.$$

Clearly, $V(\gamma) \leq M < \infty$.

Lemma 2.1. Let $\gamma : [a, b] \rightarrow \mathbb{C}$ be of bounded variation. Then,

1. If \mathcal{P}, \mathcal{Q} are partitions of $[a, b]$ with $\mathcal{P} \subseteq \mathcal{Q}$, then $v(\gamma; \mathcal{P}) \leq v(\gamma; \mathcal{Q})$.
2. If $\sigma : [a, b] \rightarrow \mathbb{C}$ is also of bounded variation and $\alpha, \beta \in \mathbb{C}$, then $\alpha\gamma + \beta\sigma$ is of bounded variation and

$$V(\alpha\gamma + \beta\sigma) \leq |\alpha|V(\gamma) + |\beta|V(\sigma).$$

We omit the proof of the above, which is direct on using the triangle inequality on the definition of $v(\gamma; \mathcal{P})$.

Lemma 2.2. If $\gamma : [a, b] \rightarrow \mathbb{C}$ is piecewise smooth, γ is of bounded variation and

$$V(\gamma) = \int_a^b |\gamma'(t)| \, dt.$$

Proof. It suffices to show the required in the case where γ is smooth, since in general we can consider the refinement of any partition that splits along the pieces along which γ is smooth.

The right hand side is well-defined since γ' is continuous. Let $\mathcal{P} = \{a = t_0 < t_1 < \cdots < t_{m-1} < t_m = b\}$. By

definition,

$$\begin{aligned} v(\gamma, \mathcal{P}) &= \sum_{k=1}^m |\gamma(t_k) - \gamma(t_{k-1})| \\ &= \sum_{k=1}^m \left| \int_{t_{k-1}}^{t_k} \gamma'(t) dt \right| \\ &\leq \sum_{k=1}^m \int_{t_{k-1}}^{t_k} |\gamma'(t)| dt = \int_a^b |\gamma'(t)| dt. \end{aligned}$$

Therefore, $V(\gamma) \leq \int_a^b |\gamma'(t)| dt$, so γ is of bounded variation.

Since γ' is continuous, it is uniformly continuous. So, if $\epsilon > 0$, we may choose $\delta_1 > 0$ such that

$$|s - t| < \delta_1 \implies |\gamma'(s) - \gamma'(t)| < \epsilon.$$

Also, let $\delta_2 > 0$ such that if $\|P\| < \delta_2$, then

$$\left| \int_a^b |\gamma'(t)| dt - \sum_{k=1}^m |\gamma'(\tau_k)|(t_k - t_{k-1}) \right| < \epsilon,$$

where τ_k is any point in $[t_{k-1}, t_k]$. Therefore,

$$\begin{aligned} \int_a^b |\gamma'(t)| dt &\leq \epsilon + \sum_{k=1}^m |\gamma'(\tau_k)|(t_k - t_{k-1}) \\ &= \epsilon + \sum_{k=1}^m \left| \int_{t_{k-1}}^{t_k} \gamma'(\tau_k) dt \right| \\ &\leq \epsilon + \sum_{k=1}^m \left| \int_{t_{k-1}}^{t_k} (\gamma'(\tau_k) - \gamma'(t)) dt \right| + \sum_{k=1}^m \left| \int_{t_{k-1}}^{t_k} \gamma'(t) dt \right|. \end{aligned}$$

If $\|P\| < \delta = \min(\delta_1, \delta_2)$, then $|\gamma'(\tau_k) - \gamma'(t)| < \epsilon$ for all $t \in [t_{k-1}, t_k]$ and

$$\begin{aligned} \int_a^b |\gamma'(t)| dt &\leq \epsilon + \epsilon(b - a) + \sum_{k=1}^m |\gamma(t_k) - \gamma(t_{k-1})| \\ &= \epsilon(1 + b - a) + V(\gamma; P) \leq \epsilon(1 + b - a) + V(\gamma), \end{aligned}$$

so we are done since $1 + b - a > 0$ is finite and ϵ can be made arbitrarily small. ■

Theorem 2.3. Let $\gamma : [a, b] \rightarrow \mathbb{C}$ be of bounded variation and suppose that $f : [a, b] \rightarrow \mathbb{C}$ is continuous. Then, there exists a (unique) complex number \mathcal{I} such that for every $\epsilon > 0$, there exists $\delta > 0$ such that when $\mathcal{P} = \{t_0 < t_1 < \dots < t_m\}$ is a partition of $[a, b]$ with $\|P\| = \max_{1 \leq k \leq m} (t_k - t_{k-1}) < \delta$,

$$\left| \mathcal{I} - \sum_{k=1}^m f(\tau_k)(\gamma(t_k) - \gamma(t_{k-1})) \right| < \epsilon$$

for any choice of points τ_k with $t_{k-1} \leq \tau_k \leq t_k$.

This \mathcal{I} is called the integral of f with respect to γ over $[a, b]$ and is denoted by

$$\mathcal{I} = \int_a^b f d\gamma = \int_a^b f(t) d\gamma(t).$$

Proof. First of all, note that it suffices to consider the case where γ is real-valued, since we can write $\gamma = \gamma_1 + \iota\gamma_2$, where γ_1, γ_2 are real-valued, to get two integrals $\mathcal{I}_1, \mathcal{I}_2$ (for γ_1, γ_2 respectively), and finally use the triangle inequality to get $\mathcal{I} = \mathcal{I}_1 + \iota\mathcal{I}_2$. ■
